

USER INTERFACE TECHNIQUE FOR SELECTION AND ACTIVATION OF  
WIRELESS SERVICES FROM AMONG MULTIPLE TRANSPORT CARRIERS

ABSTRACT

5

A method and device are provided for handling network activation between a computer and a carrier. In one example, the method involves receiving a command to initiate network activation procedures. The network activation status of the  
10 computer is then determined. If the computer is network enabled, a request is sent to a device having network activation information. The network activation information is received from the device. The computer is then configured with the network activation information in order to establish  
15 network activation with the carrier.
